• I will consider the problem of estimating the effect of some exposure *A* on an outcome *Y* based on data from an observational study.

Introduction A dissection of the problem Proposal Numerical results Discussion Introduction (1)

- I will consider the problem of estimating the effect of some exposure *A* on an outcome *Y* based on data from an observational study.
- Exposed and unexposed subjects in such studies usually differ in many observed (pre-exposure) characteristics *L*.
- This can make it difficult to make contrasts of the mean outcome between exposed and unexposed subjects with the same characteristics.

Introduction A dissection of the problem Proposal Numerical results Discussion Introduction (1)

- I will consider the problem of estimating the effect of some exposure *A* on an outcome *Y* based on data from an observational study.
- Exposed and unexposed subjects in such studies usually differ in many observed (pre-exposure) characteristics *L*.
- This can make it difficult to make contrasts of the mean outcome between exposed and unexposed subjects with the same characteristics.
- The curse of dimensionality thus forces us to adopt some form of modelling.
- E.g. a linear model

 $E(Y|A,L) = \psi A + \beta' L$

◆□ ▶ ◆□ ▶ ◆□ ▶ ◆□ ▶ ● ● ●

- Adjusting for all available characteristics *L* can be detrimental, or even impossible.
- · It can inflate bias and variance.

(a)

- Adjusting for all available characteristics *L* can be detrimental, or even impossible.
- · It can inflate bias and variance.

- There may be more covariates than observations.
- This is not uncommon, considering the possible need for interactions or other higher-order terms...

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ - 日 ・

• Stepwise variable selection strategies and penalisation methods (e.g. the lasso) are therefore routinely employed.

- Stepwise variable selection strategies and penalisation methods (e.g. the lasso) are therefore routinely employed.
- One common strategy is to adjust for *L* iff it is significantly associated with outcome, conditional on exposure, at e.g. the 5% level.
- A related common strategy is the lasso, without penalisation of the exposure effect.

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト

- One common strategy is to adjust for *L* iff it is significantly associated with outcome, conditional on exposure, at e.g. the 5% level.
- A related common strategy is the lasso, without penalisation of the exposure effect.
- How well does this work?

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト

- Suppose that the exposure has no effect.
- Suppose that *L* has a moderate effect on outcome, but a strong effect on exposure.
- Then when fitting model

 $E(Y|A,L) = \psi A + \beta L$

one will typically have little power to detect that $\beta \neq 0$.

◆□ ▶ ◆□ ▶ ◆□ ▶ ◆□ ▶ ● ● ●

- Suppose that the exposure has no effect.
- Suppose that *L* has a moderate effect on outcome, but a strong effect on exposure.
- Then when fitting model

 $E(Y|A,L) = \psi A + \beta L$

one will typically have little power to detect that $\beta \neq 0$.

- Upon removing *L* from the model, one is likely to find 'strong evidence' of an exposure effect.
- This can result in highly inflated Type I error rates

- We therefore say that convergence of the test statistic to a normal limit (centered around the truth) is non-uniform.
- · Lack of uniform convergence is a concern.
- It implies that we can never guarantee that the procedure will do well in finite samples.

・ コット (雪) ・ (目) ・ ヨ)

Introduction A dissection of the problem Proposal Numerical results Discussion Outcome-based selection (n = 1000)

R2y: R^2 of Y-L association; R2a: R^2 of A-L association

 One key reason why this procedure is problematic, is that it prioritises the exposure: it prioritises the elimination of covariates over the elimination of the exposure.

(Robins and Greenland, 1986)

• This problem can be overcome using propensity scores.

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ - 日 ・

- Consider stepwise selection in a propensity score model, then regressing outcome on exposure and propensity score.
- By always adjusting for the propensity score, this strategy does not prioritise the exposure.

・ コット (雪) ・ (目) ・ ヨ)

- Consider stepwise selection in a propensity score model, then regressing outcome on exposure and propensity score.
- By always adjusting for the propensity score, this strategy does not prioritise the exposure.
- With linear models for *Y* and *A*, and a single covariate *L*, this strategy is tantamount to adjusting for *L* iff it is significantly associated with exposure, at e.g. the 5% level.

- The conclusion so far is that propensity-score based selection is much less vulnerable to Type I error inflation than outcome-based selection.
- Problem solved?

▲□▶▲□▶▲□▶▲□▶ □ のQで

- The conclusion so far is that propensity-score based selection is much less vulnerable to Type I error inflation than outcome-based selection.
- Problem solved?
- · Its typical conservatism implies a lack of power.
- What if there are many covariates?
- What if the models are non-linear?

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト

- The conclusion so far is that propensity-score based selection is much less vulnerable to Type I error inflation than outcome-based selection.
- Problem solved?
- · Its typical conservatism implies a lack of power.
- What if there are many covariates?
- What if the models are non-linear?
- In view of this, the aim of this talk will be to develop uniformly valid tests that incorporate selection.
- · The propensity score will continue to play a crucial role...

 This problem of post-selection inference has been quite thoroughly studied for some selection strategies.

(e.g. Leeb and Pötscher, 2005; Berk et al., 2013; Taylor et al., 2014; ...)

• Most proposed solutions infer the distribution of the estimator or test statistic after selection.

(e.g. Claeskens and Hjört, 2006)

- This has the disadvantage that the results
 - · are often complex,
 - · not immediately accessible for routine data analysis,
 - · and sometimes dependent on the choice of procedure.

· Inspired by others,

(Chernozhukov et al., 2017; Farrell, 2015)

I will instead propose specific tests for treatment effect in combination with a specific selection strategy.

• Their combination is such that the test statistic converges uniformly to a normal distribution centred at the truth.

Introduction A dissection of the problem Proposal Numerical results Discussion Double-robust estimation

· Consider the test statistic

$$\frac{1}{\sqrt{n}}\sum_{i=1}^{n} \left\{ A_{i} - \pi(L_{i};\gamma) \right\} \left\{ Y_{i} - m(L_{i};\beta) \right\}$$

where we use

• a parametric propensity score model A:

 $\boldsymbol{E}(\boldsymbol{A}|\boldsymbol{L})=\pi(\boldsymbol{L};\boldsymbol{\gamma})$

e.g. $expit(\gamma' L)$ for binary A.

• a parametric outcome model B:

 $E(Y|L) = m(L;\beta)$

e.g. $\beta' L$ for continuous *Y*.

▲□▶▲□▶▲□▶▲□▶ □ のので

Introduction A dissection of the problem Proposal Numerical results Discussion Double-robust estimation

· Consider the test statistic

$$\frac{1}{\sqrt{n}}\sum_{i=1}^{n} \left\{ A_{i} - \pi(L_{i};\gamma) \right\} \left\{ Y_{i} - m(L_{i};\beta) \right\}$$

where we use

• a parametric propensity score model A:

 $\boldsymbol{E}(\boldsymbol{A}|\boldsymbol{L})=\pi(\boldsymbol{L};\boldsymbol{\gamma})$

e.g. $expit(\gamma' L)$ for binary A.

• a parametric outcome model B:

 $E(Y|L) = m(L;\beta)$

e.g. $\beta' L$ for continuous *Y*.

- This test statistic has mean zero under the null when either model \mathcal{A} or model \mathcal{B} is correct.
- We therefore call it double-robust.

(Robins and Rotnkitzky, 2001; see Rotnitzky and Vansteelandt, 2014, for a review),

(Avagyan and Vansteelandt, 2017; Dukes, Avagyan and Vansteelandt, 2018)

• Standard choices of penalty (of the order $\sqrt{\log(p)/n}$) make these gradients sufficiently close to zero.

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト

Introduction A dissection of the problem Proposal Numerical results Discussion Example - Y continuous, A binary

- Consider models $\pi(L; \gamma) = \operatorname{expit}(\gamma'L)$ and $m(L; \beta) = \beta'L$.
- Then we estimate γ and β as the solutions to

$$0 = \frac{1}{n} \sum_{i=1}^{n} \{A_i - \operatorname{expit}(\gamma' L_i)\} L_i + \lambda_\gamma \delta |\gamma|^{\delta - 1} \circ \operatorname{sign}(\gamma)$$
$$0 = \frac{1}{n} \sum_{i=1}^{n} w_i(\gamma) \{Y_i - \beta' L_i\} L_i + \lambda_\beta \delta |\beta|^{\delta - 1} \circ \operatorname{sign}(\beta)$$

where $w_i(\gamma) = \operatorname{expit}(\gamma' L_i) \{1 - \operatorname{expit}(\gamma' L_i)\}.$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQの

- In practice, we let $\delta \rightarrow$ 1+ and solve the following problems:

$$\min_{\gamma} \mathcal{F}(\gamma) = \frac{1}{n} \sum_{i=1}^{n} \log\{1 + \exp(\gamma' L_i)\} - A_i(\gamma' L_i) + \lambda_{\gamma} ||\gamma||_1$$
$$\min_{\beta} \mathcal{F}(\beta) = \frac{1}{2n} \sum_{i=1}^{n} [\hat{w}_i \{Y_i - \beta' L_i\}^2] + \lambda_{\beta} ||\beta||_1$$

- Components of $\hat{\eta}$ may be shrunk to zero, in view of which we recommend refitting the selected model.
- · The test statistic is then

$$T_n = \frac{\frac{1}{n} \sum_{i=1}^{n} \{A_i - \operatorname{expit}(\hat{\gamma}' L_i)\} \{Y_i - \hat{\beta}' L_i\}}{\sqrt{\frac{1}{n} \{\frac{1}{n-1} \sum_{i=1}^{n} [\{A_i - \operatorname{expit}(\hat{\gamma}' L_i)\} \{Y_i - \hat{\beta}' L_i\}]^2\}}}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQの

Introduction A dissection of the problem Proposal Numerical results Discussion Asymptotic properties - both models correct

- Let s_{γ} and s_{β} be the sparsity indices of models \mathcal{A} and \mathcal{B} .
- Suppose that (in addition to mild regularity conditions), the following sparsity assumptions hold:
 (i) s_γ log(p) = o(n)
 (ii) s_β log(p) = o(n)
 (iii) s_γs_β log²(p) = o(n).

Theorem When model A and B are correct, the test statistic T_n converges uniformly to a standard normal distribution.

・ コット (雪) ・ (目) ・ ヨ)

Introduction A dissection of the problem Proposal Numerical results Discussion A closer look at the conditions...

- Conditions
 - (i) $s_{\gamma} \log(p) = o(n)$ (ii) $s_{\beta} \log(p) = o(n)$ are quite standard to guarantee consistency of the lasso-based estimators.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQの

- Conditions
 - (i) $s_{\gamma} \log(p) = o(n)$
 - (ii) $s_\beta \log(p) = o(n)$

are quite standard to guarantee consistency of the lasso-based estimators.

• Condition (iii) $s_{\gamma}s_{\beta}\log^2(p) = o(n)$

determines the rate of convergence of the estimators.

• It suggests that if one model is sparse, the other can be more dense.

Conditions

(i) $s_{\gamma} \log(p) = o(n)$

(ii) $s_{\beta} \log(p) = o(n)$

are quite standard to guarantee consistency of the lasso-based estimators.

• Condition (iii) $s_{\gamma}s_{\beta}\log^2(p) = o(n)$

determines the rate of convergence of the estimators.

- It suggests that if one model is sparse, the other can be more dense.
- When evaluating medical treatments, this is arguably satisfied as clinicians may use a limited number of variables to decide on treatment, whereas outcome may be affected by many more.

Compared with other recent proposals from high-dimensional inference in GLMs:

(van de Geer et al., 2014; Belloni et al., 2016)

• We have weakened the assumptions on sparsity by making use of double robustness.

(see also Farrell, 2015, for the ATE)

• Other approaches usually require ultra-sparsity, e.g. $s_{\gamma}\sqrt{\log(p)} = o(\sqrt{n})$ instead of $s_{\gamma}\log(p) = o(n)$.

・ロト ・ 一日 ・ ・ 日 ・ ・ 日 ・

Compared with other recent proposals from high-dimensional inference in GLMs:

(van de Geer et al., 2014; Belloni et al., 2016)

• We have weakened the assumptions on sparsity by making use of double robustness.

(see also Farrell, 2015, for the ATE)

- Other approaches usually require ultra-sparsity, e.g. $s_{\gamma}\sqrt{\log(p)} = o(\sqrt{n})$ instead of $s_{\gamma}\log(p) = o(n)$.
- Unlike others, we do not require sample-splitting to obtain weaker rates.

(Chernozhukov et al., 2017)

・ロト ・ 一日 ・ ・ 日 ・ ・ 日 ・

Suppose that (in addition to the previous conditions), the following sparsity assumptions hold: (iv) Either (a) $s_{\gamma}\sqrt{\log(p)} = o(\sqrt{n})$ (if model \mathcal{A} is correct) or (b) $s_{\beta}\sqrt{\log(p)} = o(\sqrt{n})$ (if model \mathcal{B} is correct).

Theorem

When model A or B is correct, the test statistic T_n converges uniformly to a standard normal distribution.

Note the tradeoff between modelling and sparsity conditions.

・ コット (雪) ・ (目) ・ ヨ)

 Other proposals from high-dimensional inference in GLMs assume A and B to be linear, and B to be correctly specified and ultra-sparse.

(van de Geer et al., 2014; Belloni et al., 2016; Shah and Bühlmann, 2017)

- · By using specific bias-reduction strategies, our tests
 - allow arbitrary conditional mean models for \mathcal{A} and \mathcal{B} ,
 - remain valid when $\mathcal A$ or $\mathcal B$ is misspecified,
 - use weaker sparsity assumptions.

 Other proposals from high-dimensional inference in GLMs assume A and B to be linear, and B to be correctly specified and ultra-sparse.

(van de Geer et al., 2014; Belloni et al., 2016; Shah and Bühlmann, 2017)

- By using specific bias-reduction strategies, our tests
 - allow arbitrary conditional mean models for \mathcal{A} and \mathcal{B} ,
 - remain valid when \mathcal{A} or \mathcal{B} is misspecified,
 - use weaker sparsity assumptions.
- · Weaker sparsity assumptions do not suffice for Wald tests.

- *n* = 200
- linear models with $Z_1, ..., Z_p$ for p = 140 mutually independent, standard normal variates.
- 19 confounders, generally strongly associated with exposure, and more weakly with outcome.
- · No pure exposure predictors.
- 40 pure outcome predictors.
- Covariates explain 80% of the variability in exposure and outcome.
- 1000 simulation experiments.
- Penalty parameters chosen via cross-validation (1 SE).

- Routine outcome-based variable selection strategies are problematic.
- Propensity-score-based selection has much greater validity, but is not guaranteed to result in tests with the nominal size.

• For testing the null, we have shown that weaker conditions are attainable without the need for sample-splitting.

- For testing the null, we have shown that weaker conditions are attainable without the need for sample-splitting.
- We have extended this to allow for model misspecification.
- This required the use of special 'bias-reduced' fitting strategies. (Vermeulen and Vansteelandt, 2015)
